What is a Force Field?

$$U(x_1, x_2, x_3, ..., x_n)$$

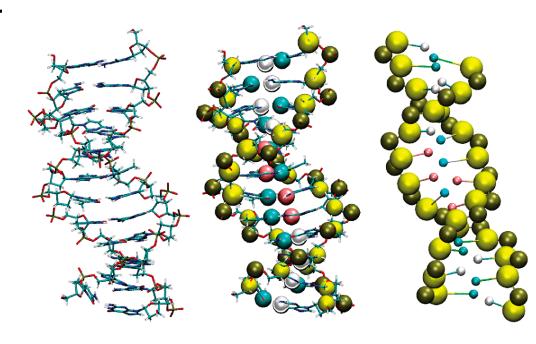

$$F(\vec{x}) = -\left[\frac{\partial U(\vec{x})}{\partial x_1}, \frac{\partial U(\vec{x})}{\partial x_2}, ..., \frac{\partial U(\vec{x})}{\partial x_n}\right]$$

- Any way to assign an energy to the coordinates of particles in the system
- You can compute the force and use for MD as long as the system has continuous derivatives.
- Pick a U(x) that is good enough for your purposes.
- If you define a U(x), you also define an F(x), which assigns a vector (the force) to each configuration in space.
 - Thus, it is a **vector field**, where the vector is the force!

What are we trying to simulate?

- We have some MODEL of our molecule.
- We have the hypothesis that the physical behavior only depends on SOME of the physics of the molecule
- We test that hypothesis with a simulation

- Can be atomistic, quantum mechanical, or coarse grained.
 - In CG, each particle isn't an atom, but a methane particle, or an amino acid.

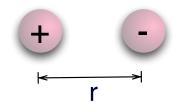

We break up the potential energy into classical terms, and fit the resulting

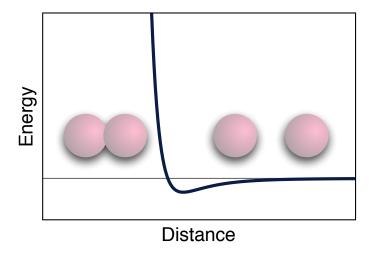

Most common nonbonded force fields are pairwise

$$V(r_1, r_2, ..., r_n) = \sum_{i < j} V_{ij}(r_{ij})$$

$$U(\mathbf{x}) = \sum_{\text{all pairs}} \frac{q_i q_j}{r}$$

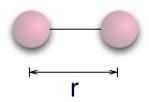

$$+\sum_{ ext{all pairs}}rac{A_{ij}}{r^{12}}-rac{B_{ij}}{r^6}$$

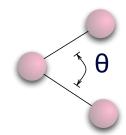

"Bonded Terms"

 We replace the electrons in orbitals with simple functional forms that are 10⁶ times cheaper (but WAY more approximate).

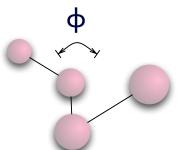

$$+ \sum_{\text{all bonds}} \frac{1}{2} K_b \left(r - r_0 \right)^2$$

$$+ \sum_{\text{all angles}} \frac{1}{2} K_{\theta} \left(\theta - \theta_0\right)^2$$

+
$$\sum_{\text{all torsions}} \sum_{n} K_{\phi} \left[1 - \cos \left(n\phi + \phi_0 \right) \right]$$

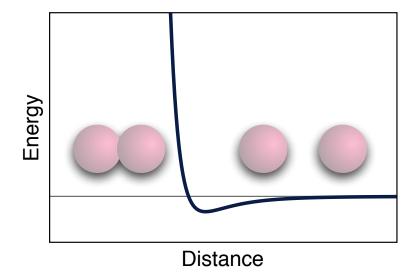

"Nonbonded terms"

We replace the electrostatic / dipole / induced dipole interactions with physically motivated (but not exact) functional forms.

$$U(\mathbf{x}) = \sum_{\text{all pairs}} \frac{q_i q_j}{r} + \sum_{\text{all pairs}} \frac{A_{ij}}{r^{12}} - \frac{B_{ij}}{r^6}$$

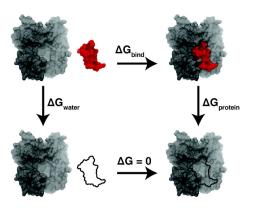

$$+\sum_{\text{all pairs}} \frac{A_{ij}}{r^{12}} - \frac{B_{ij}}{r^6}$$

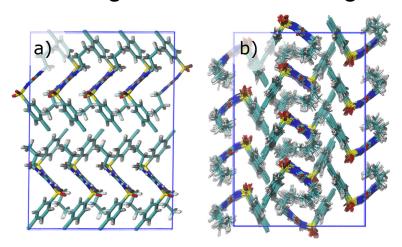

Small molecule force fields are widely-used tools in computational biophysics and soft

 Surprisingly, all-atom fixed charge force fields strike an appropriate balance between chemical accuracy and computation efficiency for many systems of interest.

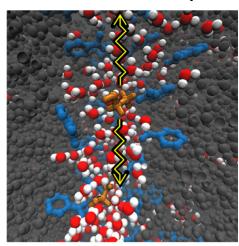

Protein-Ligand Binding

Drug molecule screening

Molecular transport

"Bonded Terms"

 We replace the energies of electrons jiggling in molecular orbitals with simple functional forms that are 10⁶ times cheaper (but WAY more approximate).

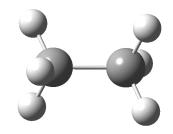

$$+\sum_{\text{all bonds}} \frac{1}{2} K_b (r - r_0)^2 + \sum_{\text{all angles}} \frac{1}{2} K_\theta (\theta - \theta_0)^2$$

- Most common are harmonic bonds and angles
- Pretty good approximation to quantum mechanics!
- Can get the parameters directly from QM of isolated molecules, as they are relatively independent of environment

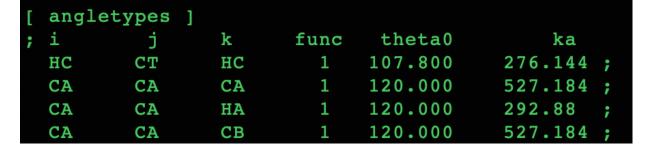

Bonds and Angles

$$+ \sum_{\text{all bonds}} \frac{1}{2} K_b (r - r_0)^2$$

```
+\sum_{\text{all angles}} \frac{1}{2} K_{\theta} (\theta - \theta_0)^2
```

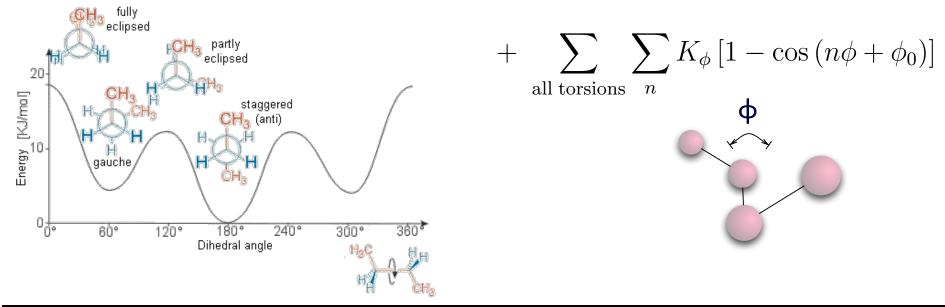

Bonds and Angles

- Bonds
 - Could use $U(x) = k_2(r r_0)^2 + k_4(r r_0)^4$
 - Fancier terms
- Angles:
 - Could add Urey-Bradley term
 - $U(x) = k_{\theta}(\theta \theta_0)^2 + k_{UB}(r_{ik} r_u b)^2$
 - ML potentials

Torsions, or the junk bin of force fields

Approximate QM with a sum of periodic trig funcions

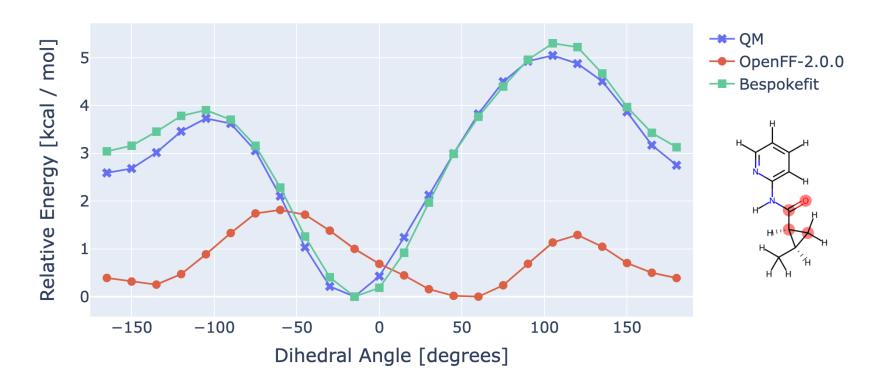

[dihedrals]							
;ai	аj	ak	al	funct	phi	k	
51	54	57	60	1	0.00000000000	1.796983533954	3
51	54	57	60	1	180.000000000000	1.064375944885	2
51	54	57	60	1	180.000000000000	3.655209445001	1

 Even more annoyingly, there are at least 3 different equivalent representations of dihedrals

It can be difficult to get these right!

 NOTE: the energy of changing the torsion is not JUST the torsional potential, but involves things like the nonbonded interaction between atoms i and l.

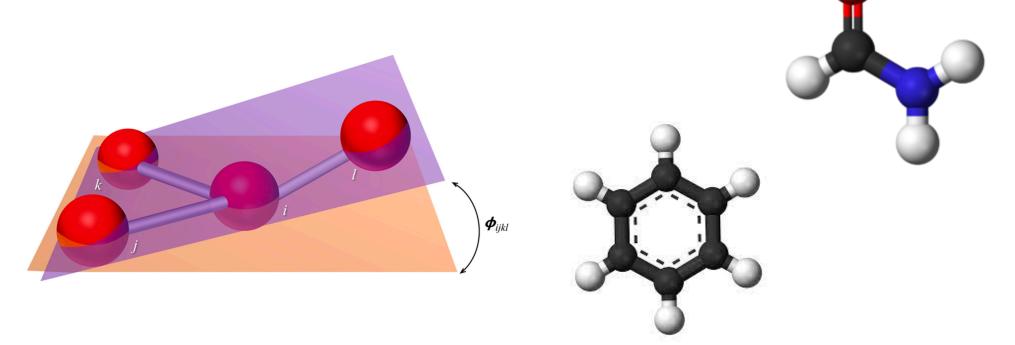

Improper torsions

A ways to keep things with conjugated double bonds

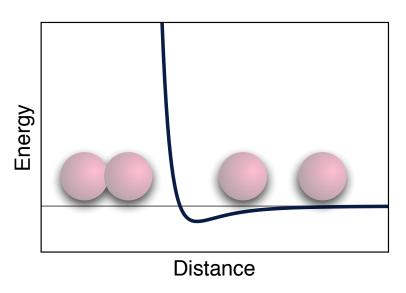

planar

Lennard-Jones terms

$$U(r_{ij}) = 4\epsilon \left(\left(\frac{\sigma_{ij}}{r_{ij}} \right)^{12} - \left(\frac{\sigma_{ij}}{r_{ij}} \right)^{6} \right)$$

```

                        1.00800
```

 This just has sigma and epsilon for O and H. What about the O-H interaction???

Lots of different, equivalent ways to write Lennard-Jones parameters!

$$U(r_{ij}) = 4\epsilon \left(\left(\frac{\sigma_{ij}}{r_{ij}} \right)^{12} - \left(\frac{\sigma_{ij}}{r_{ij}} \right)^{6} \right)$$

$$U(r_{ij}) = \frac{A_{ij}}{r^{12}} - \frac{B_{ij}}{r^6}$$

Combining rules

```

nbfunc
             comb-rule gen-pairs
                                           fudgeLJ fudgeQQ
                                           0.5
                                                   0.5
                            yes
```

Geometric

$$\epsilon_{ij} = \sqrt{\epsilon_i \epsilon_j}$$

$$\sigma_{ij} = \sqrt{\sigma_i \sigma_j}$$

$$\epsilon_{ij} = \sqrt{\epsilon_i \epsilon_j}$$

Lorentz-Berthelot
$$\epsilon_{ij} = \sqrt{\epsilon_i \epsilon_j}$$
 $\sigma_{ij} = \frac{1}{2} \left(\sigma_i + \sigma_j \right)$

Works better than it should (but not perfect)

Exclusions?

- What about atoms separated by no bonds (1,2)?
- What about atoms separated by 1 φ
 bond (1,3)?
- What about atoms separated by 2 bonds (1,4)?

Virtual Sites

Constrains

Other terms you could put in:

- Hydrogen bonding terms
- Polarizability
 - The ability for charge distributions to rearrange.
- Other many body terms (charge penetration)
- Force field that break bonds (ReaxFF)
- Machine learning terms (ANI multibody neural net potentials, many others.
- BUT pairwise nonbonded potentials (plus some multibody bonded terms) are **much** faster than general multibody terms for both MD and MC.
- As long as you have a function* U(x₁,x₂,x₃...x_N), an energy output with a coordinate input, you can do molecular dynamics (or Monte Carlo!)

How do you choose force field parameters

- Nonbonded parameters
- Charges:
 - Match to electrostatics potential (RESP)
 - With maybe some tweaks
 - AM1 with bond charge corrections (AM1-BCC)
- van der Waals
 - Match thermodynamic properties of liquids
 - Densities, enthapies of vaporization or mixing + others

What sorts of force fields are out there?

OPLS-AA / OPLS-UA

- Small molecules, proteins
- Evolved out of Bill Jorgensen's work
- Now run by Schrödinger
- Biomolecules and small molecule ligands

TRAPPE

- Coming mostly from Ilja Siepmann's group
- Designed for phase equilibrium

Other Force Fields

CHARMM

- Evolved from the work in Martin Karplus's group at Harvard over ~50 years.
- Alex MacKerrell (Maryland) and Benoit Roux (Chicago) are longest contributing developers but MANY more.
- Proteins, lipids, nucleic acids small molecules

AMBER

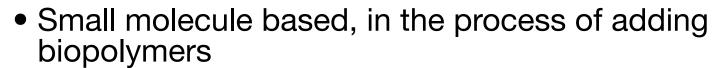

- Evolved from the work in Peter Kollman's group at UCSF, and his academic descendants.
- GAFF small molecule force field (Junmei Wang)
- Proteins and nucleic acids

Other Force Fields

Open Force Field

- http://www.openforcefield.org
- New effort, focused on open software as force fields

- Can build from SMILES, sdf, mol2
- Difference is: it matches molecular parameters in a more general way and DOESN'T use atom types

Force Field Assignment Tools

- AmberTools/tleap
- CHARMM-GUI/CGENFF
- OpenFF toolkit
- foyer
- pysimm (polymers)
- OpenKIM (metals)

Other Force Fields

- What about polymers?
 - OPLS often used.
 - COMPASS
 - MMFF
- What about metals?
 - Lots of metal specific functional forms.
 - Generally requires more complicated interactions than the simple nonbonded potentials

But What Force Field Should I Use?

 The one that allows you to test the hypothesis that you want to

OR

- The one that is validated as an effective screening mechanism to predict the property of interest to other researchers.
- Has the force field I want to use been validated on sufficiently similar systems?
- "All models are wrong. Some models are useful."
